

**CONCEPT: GLUCOSE ACTIVE SYMPORTER MODEL**

• Classic & relevant example of *secondary active transport* are *intestinal epithelial Na<sup>+</sup>-Glucose* \_\_\_\_\_.

**A** Primary Active Transport: \_\_\_\_\_ / \_\_\_\_\_ pump maintains transmembrane Na<sup>+</sup> gradient.

**B** Secondary Active Transport: Na<sup>+</sup>-Glucose symporters \_\_\_\_\_ Na<sup>+</sup> & glucose in *same* direction.

□ \_\_\_\_\_ Na<sup>+</sup> imported \_\_\_\_\_ their gradient *powers* \_\_\_\_\_ glucose imported \_\_\_\_\_ its gradient.

**C** As glucose is pumped into epithelial cell, it is simultaneously moved into the blood via a GLUT2 \_\_\_\_\_.

□ Na<sup>+</sup>-Glucose symporter & GLUT2 uniporter operate on \_\_\_\_\_ sides of epithelial cells.

**EXAMPLE:** Intestinal Epithelial Glucose Active Symporter.

**PRACTICE:** Which of the following is TRUE about the Na<sup>+</sup>-glucose symporter?

- The transporter moves glucose down its concentration gradient.
- The transporter is directly powered by ATP hydrolysis.
- The energy stored in the Na<sup>+</sup> gradient is harvested for the movement of glucose.
- The energy stored in the glucose gradient is harvested for the movement of K<sup>+</sup>.
- The protein is an ABC transporter.

**CONCEPT: GLUCOSE ACTIVE SYMPORTER MODEL**

**PRACTICE:** The Na<sup>+</sup>-Glucose symporter effectively transports glucose inside of cells against its concentration gradient using energy stored in the Na<sup>+</sup> concentration gradient. This energy for glucose transport is derived from the \_\_\_\_\_.

- a) Glucose-Na<sup>+</sup> antiporter.
- b) Na<sup>+</sup>-K<sup>+</sup>-ATPase.
- c) Chloride-bicarbonate antiporter.
- d) Glucose erythrocyte uniporter (GLUT1).
- e) Epithelial glucose uniporter (GLUT2).
- f) SERCA pump.

**PRACTICE:** The Na<sup>+</sup>-Glucose symporter transports the two molecules into the cell, while the Na<sup>+</sup>-K<sup>+</sup> ATPase uses ATP to transport Na<sup>+</sup> ions out of the cell. What would be the result of a mutation leading to a nonfunctional Na<sup>+</sup>-Glucose symporter?

- a) Increased levels of intracellular K<sup>+</sup>.
- b) Increased levels of intracellular glucose.
- c) Decreased activity of the Na<sup>+</sup>-K<sup>+</sup> ATPase.
- d) Overactivation of the Na<sup>+</sup>-K<sup>+</sup> ATPase.
- e) Increased levels of ATP.

**PRACTICE:** Imagine that you perform a series of experiments to test the rate of glucose transport ( $V_0$ ) into epithelial cells using the Na<sup>+</sup>-Glucose symporters. These experimental epithelial cells contain no intracellular Na<sup>+</sup> but have the same glucose concentration as their surroundings. In experiment #1, you transfer your cells to test tubes that contain different extracellular [Na<sup>+</sup>] & then measure the rate of glucose transport ( $V_0$ ). In experiment #2, you introduce leakage Na<sup>+</sup> channels into the cell membranes & then repeat the same experiment. Label the data on the plot below as showing results to either Experiment #1 or Experiment #2.
