

TOPIC: SPECIAL RIGHT TRIANGLES

45-45-90 Triangles

◆ In triangles with 45° angles, the 2 legs are always the _____ length.

► The hypotenuse will always be a multiple of the leg length, which you can find using:

Recall

$$a^2 + b^2 = c^2$$

New

$$\text{hyp} = \text{leg} \cdot \underline{\hspace{1cm}}$$

(45 – 45 – 90)

EXAMPLE

Solve for the unknown side(s) of each triangle.

(A)

(B)

TOPIC: SPECIAL RIGHT TRIANGLES

PRACTICE

Given the triangle below, determine the missing side(s) without using the Pythagorean Theorem (make sure your answer is fully simplified).

TOPIC: SPECIAL RIGHT TRIANGLES

30-60-90 Triangles

◆ For the 30-60-90 triangle, relate side lengths to the *shortest* leg.

Recall	45 – 45 – 90	New	30 – 60 – 90
	 $\text{hyp} = \text{leg} \cdot \sqrt{2}$ (45 – 45 – 90)		 $\text{hyp} = \text{short leg} \cdot \underline{\hspace{1cm}}$ (30 – 60 – 90) $\text{long leg} = \text{short leg} \cdot \underline{\hspace{1cm}}$ (30 – 60 – 90)

EXAMPLE

Solve for the unknown side(s) of each triangle.

TOPIC: SPECIAL RIGHT TRIANGLES

PRACTICE

Given the triangle below, determine the missing side(s) without using the Pythagorean Theorem (make sure your answer is fully simplified).
