

CONCEPT: INTRO TO HEAT ENGINES

- **Heat Engine:** Machine that converts _____ into useful _____ (e.g. a car engine!)

Hot Reservoir: Source of heat energy (Q_H) going *INTO* engine (**burning gasoline**)

Work: Usable energy (W) *produced BY* engine (**turning wheels of car**)

Cold Reservoir: Wasted heat energy (Q_C) *expelled OUT* from engine (**exhaust pipe**)

- Remember: $\Delta E_{int} = Q - W$, and in cyclic processes, $\Delta E_{int} = 0$, so $W_{cyc} = Q_{cyc}$

- Heat Engines are ALWAYS cyclic, and heat flows IN and OUT over a cycle:

$$\underline{\hspace{1cm}} = \underline{\hspace{1cm}} = \underline{\hspace{1cm}}$$

EXAMPLE: A heat engine takes in 500J of heat and does 300J of work. How much waste heat is expelled from the engine?

PROBLEM: An aircraft engine takes in 9 kJ of heat and expels 6.4 kJ of heat each cycle. How much mechanical work does the engine do each cycle?

- A) 15.4 kJ
- B) 2.6 kJ
- C) 2.6 J
- D) 6.4 kJ

HEAT ENGINES

$$\Delta E_{int} = 0$$

$$|W| = |Q_H| - |Q_C|$$

PROBLEM: A gasoline engine takes in 1.6×10^4 J of heat from gasoline combustion and does 3700 J of work per cycle. Gasoline has a latent heat of combustion $L_C = 4.6 \times 10^7$ J/kg. **a)** How much heat is expelled each cycle? **b)** What mass of fuel is burned each cycle? **c)** If the engine completes 60 cycles/sec (3600 RPM), what is its power output in kW?

HEAT ENGINES

$$\Delta E_{int} = 0$$

$$|W| = |Q_H| - |Q_C|$$

$$Q = mL$$

PROBLEM: A heat engine uses a tank of ice water as a cold reservoir. The engine takes in 8 kJ of heat from the hot reservoir, and the heat expelled melts 18g of ice in the tank. How much work does this engine do?

- A) 14,012 J
- B) 6012 J
- C) 1,988 J
- D) 8000 J

HEAT ENGINES

$$\Delta E_{int} = 0$$

$$|W| = |Q_H| - |Q_C|$$

$$Q = mL$$

$$L_f = 3.34 \times 10^5 \text{ J/kg}$$

CONCEPT: THERMAL EFFICIENCY AND THE SECOND LAW OF THERMODYNAMICS

- Remember: Heat engines produce Work using heat energy flowing from the Hot reservoir to the Cold Reservoir.

-The engine's **thermal efficiency** (___) is how _____ it is at producing Work from Heat: $e = \text{---} (\times 100\%) = 1 - \text{---}$

EXAMPLE: For the following examples below, calculate the missing variable(s).

- The Second Law of Thermodynamics has multiple “statements”.

Second Law of Thermodynamics – Kelvin / “Engine” Statement

- It is _____ to convert $Q_H \rightarrow W$ with 100% efficiency. Engines **must** expel waste heat to the cold reservoir.

PROBLEM: A steam turbine takes in 75g of water and boils it as heat energy to run a 40% efficient engine. How much work does this engine do per cycle?

- A) 67,800 J
- B) 1.695×10^5 J
- C) 10,020 J
- D) 4.24×10^5 J

HEAT ENGINES
$\Delta E_{int} = 0$ $ W = Q_H - Q_C $ $e = \frac{W}{Q_H} = 1 - \frac{Q_C}{Q_H}$ $Q = mL$ $L_f = 3.34 \times 10^5 \text{ J/kg}$ $L_v = 2.26 \times 10^6 \text{ J/kg}$

PROBLEM: A nuclear power plant produces 250 MW of power, and expels 550 MW out to the surrounding environment. What is the thermal efficiency of this power plant?

HEAT ENGINES
$\Delta E_{int} = 0$ $ W = Q_H - Q_C $ $e = \frac{W}{Q_H} = 1 - \frac{Q_C}{Q_H}$

- The efficiency equation does not depend on time, so you can use it when given units of power [W] instead of energy [J].
