

## CONCEPT: DRIFT VELOCITY & CONDUCTIVITY

- The speed of electrons through conductors is called the \_\_\_\_\_ velocity

$$\rightarrow v_d = \underline{\hspace{2cm}}$$

- $e$  is elementary charge
- $m$  is mass of electron ( $9.11 \times 10^{-31}$  kg)
- $E$  is Electric Field strength
- $\tau$  is the average time between collisions, called MEAN FREE TIME

- CURRENT can be calculated as  $\rightarrow I = e * n * A * v_d = \underline{\hspace{2cm}}$

- $n$  is FREE Electron Density (# of FREE electrons/m<sup>3</sup>)

- Current DENSITY becomes:  $\rightarrow J = \frac{I}{A} = \underline{\hspace{2cm}}$

EXAMPLE: A conductor has  $1 \times 10^{20}$  electrons per cubic meter, 1% of which are free electrons. If the electric field in the conductor is 5000N/C, and the mean free time is  $5\mu\text{s}$ , what is the current density in the conductor?

- RESISTIVITY of a conductor can be calculated as

$$\rightarrow \rho = \frac{m}{ne^2\tau}$$

- CONDUCTIVITY of a conductor can be calculated as

$$\rightarrow \sigma = \underline{\hspace{2cm}} = \underline{\hspace{2cm}}$$

EXAMPLE: Copper has a conductivity of  $5.8 \times 10^7 \Omega^{-1}\text{m}^{-1}$ . If the density of free electrons in a copper conductor is  $5 \times 10^{17}$ , what is the mean free time for the free electrons?
