

CONCEPT: Energy in Simple Pendulums

- Just like mass-spring systems, energy in pendulums → 2 types: _____ and _____.

Energy in Mass-Springs	
Amplitude:	EQ:
Elastic: Max	Elastic: 0
Kinetic: 0	Kinetic: Max
Total ME: $\frac{1}{2}kA^2$	Total ME: $\frac{1}{2}mv_{\text{max}}^2$

- For any θ , height

$$h = \underline{\hspace{2cm}}$$

Amplitude:	Equilibrium:	Any other Point:
$\theta = \underline{\hspace{2cm}}$	$\theta = \underline{\hspace{2cm}}$	$\theta = \underline{\hspace{2cm}}$
Grav. Potential = $mgh = 0 / \text{max}$	Grav. Potential = $mgh = 0 / \text{max}$	Grav. Potential = mgh
Kinetic Energy = $\frac{1}{2}mv^2 = 0 / \text{max}$	Kinetic Energy = $\frac{1}{2}mv^2 = 0 / \text{max}$	Kinetic Energy = $\frac{1}{2}mv^2$
Total M.E. = $\underline{\hspace{2cm}}$	Total M.E. = $\underline{\hspace{2cm}}$	Total M.E. = $\underline{\hspace{2cm}} + \underline{\hspace{2cm}}$

$$\text{M.E.} = \underline{\hspace{2cm}} = \underline{\hspace{2cm}} = \underline{\hspace{2cm}} + \underline{\hspace{2cm}}$$

(Energy Conservation for Pendulums)

EXAMPLE: A mass **m** is attached to a pendulum of length **L**. It is pulled up an angle θ and released. Using energy conservation, derive an expression for the maximum speed this mass experiences.

EXAMPLE: A mass of 0.400 kg hangs from a 2m pendulum. At the moment when it makes a 5° with the vertical, it has a speed of 1.5 m/s. What is the maximum height the pendulum will reach?

Pendulum SHM Equations
$ F_s = F_A = -mg\theta$ $a = -g\theta = -\frac{g}{L}x$
$\omega = 2\pi f = \frac{2\pi}{T} = \sqrt{\frac{g}{L}}$ $N \text{ [cycles]} = \frac{t \text{ [time]}}{T \text{ [Period]}} = t * f$
$\theta(t) = \theta_{max} \cos(\omega t)$ $v_{max} = \sqrt{2gL(1 - \cos \theta_{max})}$
$h = L(1 - \cos \theta)$ $M.E. = mgh_{max} = \frac{1}{2}mv_{max}^2 = mgh_p + \frac{1}{2}mv_p^2$

PRACTICE: A mass swinging at the end of a pendulum has a speed of 1.32m/s at the bottom of its swing. At the top of its swing, it makes a 9° with the vertical. What is the length of the pendulum?

Pendulum SHM Equations	
$ F_R = -mg\theta$ $a = -g\theta = -\frac{g}{L}x$	
$\omega = 2\pi f = \frac{2\pi}{T} = \sqrt{\frac{g}{L}}$ $N \text{ [cycles]} = \frac{t \text{ [time]}}{T \text{ [Period]}} = t * f$	
$\theta(t) = \theta_{max} \cos(\omega t)$ $A = L\theta$ $v_{max} = \sqrt{2gL(1 - \cos \theta_{max})}$ $\rightarrow v_{max} = A\omega$	
$h = L(1 - \cos \theta)$ $M.E. = mgh_{max} = \frac{1}{2}mv_{max}^2 = mgh_p + \frac{1}{2}mv_p^2$
